OLA RIDE ANALYTICS

Business Performance Analysis Report

Reporting Period

1 January – 30 December 2024

Tools Used

Microsoft Excel | PostgreSQL | Microsoft Power BI

EXECUTIVE SUMMARY

This report evaluates Ola's ride-booking operations using 150,000 booking records covering the period from January to December 2024. The analysis examines booking fulfilment, cancellation behaviour, vehicle performance, pickup-location activity, customer ratings, payment methods and booking value.

The analysis identified a significant gap between booking demand and successful ride fulfilment. Of the 150,000 bookings, 93,000 resulted in completed rides, representing a completion rate of 62%. The remaining 57,000 bookings did not result in completed rides.

Driver cancellations were the largest individual category of unsuccessful bookings, accounting for 27,000 cases, or 47.37% of all unsuccessful bookings. Location-level analysis also revealed differences in completion performance, with Welcome recording the highest completion rate at 66.27% and Vinobapuri the lowest at 54.68%.

The analysis further identified 48,000 records without a recorded payment method, highlighting a data-completeness issue that limits payment-related reporting. Vehicle-level comparisons showed differences in cancellation volumes and operational measures, although these differences require booking-volume-adjusted comparisons before drawing conclusions about relative performance.

The findings identify three priorities for management: improving booking fulfilment, investigating driver-side cancellation patterns and strengthening the completeness of operational data. The Power BI dashboard consolidates the major performance indicators and allows users to examine these patterns across dates, vehicle categories, pickup locations and payment methods.

1. INTRODUCTION

1.1 Business Background

For a ride-hailing platform such as Ola, booking volume alone does not represent operational success. The ability to convert customer requests into completed rides is equally important. Cancellations, driver availability issues and location-level differences in fulfilment can affect service reliability and the overall customer experience.

Understanding these operational patterns requires more than monitoring the number of bookings received. It requires examining the outcomes of bookings, identifying where unsuccessful requests occur and evaluating differences across vehicles, locations and time periods.

This report analyses Ola's ride-booking operations using 150,000 booking records from 2024 to identify operational performance patterns and areas requiring management attention.

1.2 Business Problem and Objectives

The analysis focuses on understanding the gap between booking demand and completed rides.

The primary objectives are to:

- Measure overall booking fulfilment and unsuccessful booking levels.
- Identify the major categories and recorded reasons for cancellations.
- Compare operational performance across vehicle types and pickup locations.
- Examine booking trends across dates and time periods.
- Evaluate customer ratings, payment methods and booking-value patterns.
- Identify operational and data-quality issues that warrant further investigation.
- Translate analytical findings into practical management recommendations.

1.3 Scope of the Analysis

The report covers the following areas:

- Booking demand and time-based activity.
- Completed, cancelled, incomplete and unfulfilled bookings.
- Vehicle-wise and location-wise performance.
- Customer and driver cancellation patterns.
- Customer ratings and waiting-time indicators.
- Payment-method distribution and data completeness.
- Booking value and selected ride-level comparisons.

The analysis is limited to the information available in the supplied dataset. It evaluates recorded operational patterns rather than establishing the underlying causes of every unsuccessful booking.

2. DATASET OVERVIEW AND METHODOLOGY

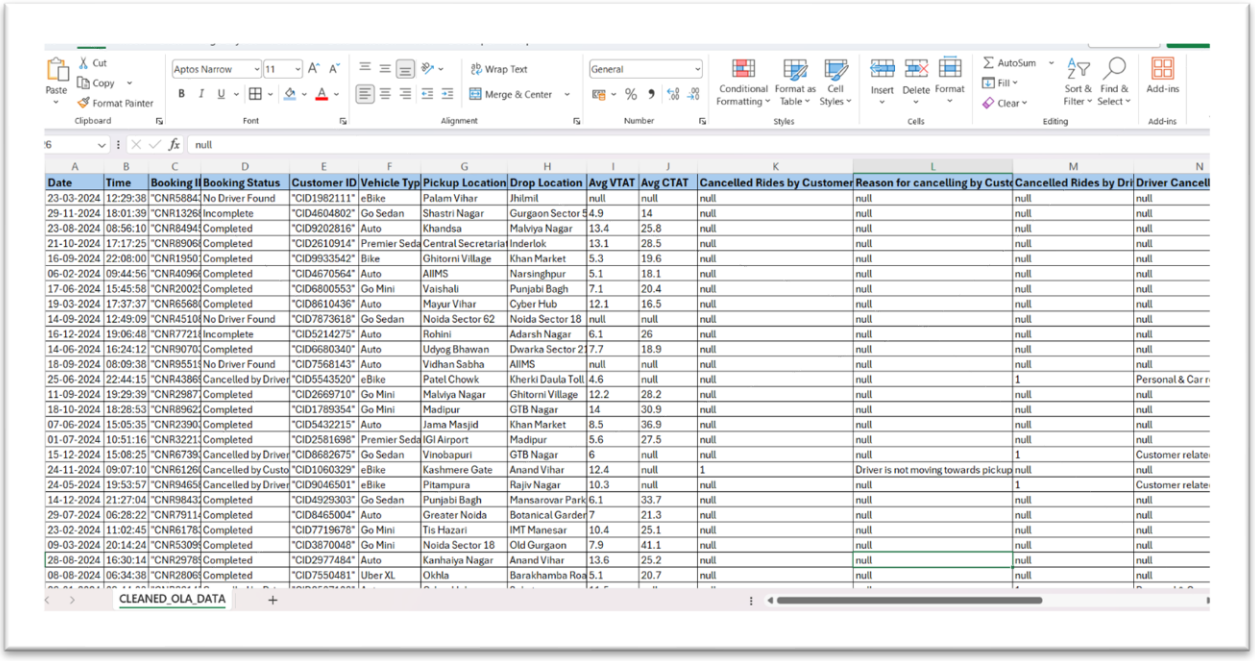

2.1 Dataset Profile

The analysis uses an Ola ride-booking dataset obtained from Kaggle.

Dataset Attribute	Details
Data Source	Kaggle
Total Records	150,000
Total Columns	21
Reporting Period	1 January – 30 December 2024
Unit of Analysis	Individual ride booking
Data Format	Structured tabular data

Each row represents an individual booking. The dataset contains booking outcomes, customer information, vehicle categories, pickup and drop-off locations, ride distances, financial details, payment methods and service-quality indicators.

Figure 1: Overview of the Ola Ride Booking Dataset

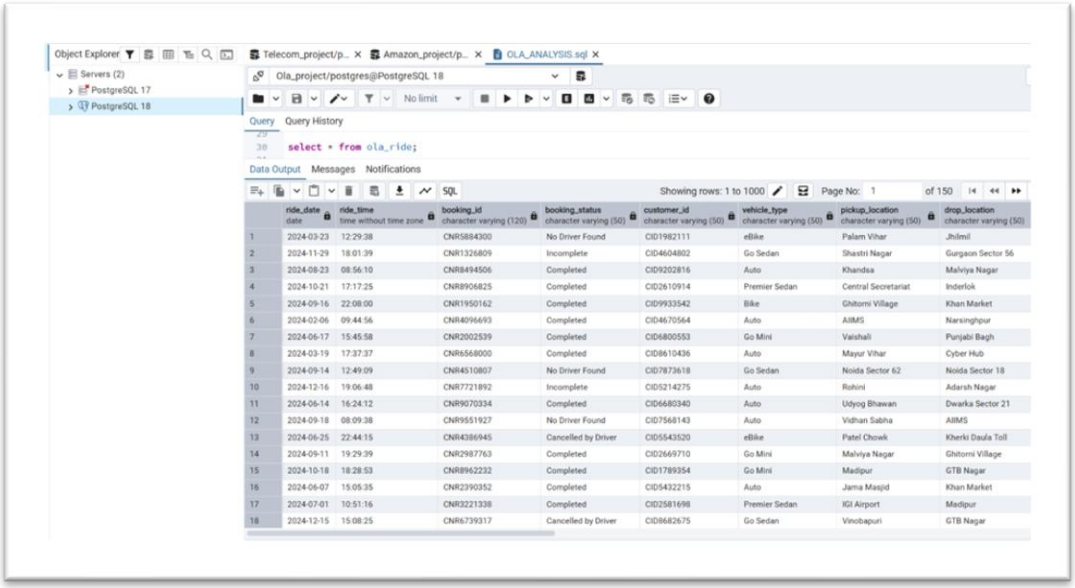

2.2 Data Structure and Business Relevance

The dataset contains several categories of information relevant to operational performance.

Data Category	Key Information	Business Relevance
Booking Details	Booking ID, date, time and status	Measures demand and fulfilment
Customer Details	Customer ID and related information	Supports customer-level analysis
Ride Operations	Vehicle type, pickup, drop-off, distance and waiting times	Evaluates operational performance
Financial Details	Booking value and payment method	Examines booking-value patterns
Cancellation Details	Cancellation status and recorded reasons	Identifies unsuccessful booking patterns
Service Quality	Customer and driver ratings	Examines service-quality indicators

The availability of these attributes allows booking outcomes to be compared across operational and customer-related dimensions.

Figure 2: Structure and Attributes of the Ola Ride Booking Dataset

2.3 Data Cleaning and Preparation

Microsoft Excel was used to prepare the original dataset before analysis.

The preparation process included:

- Reviewing the dataset structure and column consistency.
- Identifying and removing duplicate records.
- Handling missing values where appropriate.
- Correcting data formats and standardising inconsistent entries.
- Preparing the cleaned dataset for database import.

The prepared dataset was subsequently imported into PostgreSQL for analysis and used as the basis for the Power BI reporting process.

2.4 Analytical Tools and Methodology

Microsoft Excel – Data Preparation

Excel was used to clean and standardise the original dataset, ensuring consistency before database import.

PostgreSQL – Business Analysis

PostgreSQL was used to analyse the 150,000 records through 15 SQL queries. The analysis examined booking trends, fulfilment, cancellations, vehicle and location performance, payment information and booking value.

Microsoft Power BI – Performance Reporting

Power BI was used to develop an interactive dashboard presenting the major operational indicators and analytical findings. KPI cards, charts and interactive filters allow users to investigate performance across different business dimensions.

The overall approach follows a structured process of data preparation, SQL-based analysis and visual reporting.

3. BUSINESS PERFORMANCE ANALYSIS

This section presents the findings from the PostgreSQL analysis. The focus is on identifying operational patterns, comparing business performance and highlighting areas that require further investigation.

3.1 Booking Demand and Time-Based Performance

Daily booking activity ranged between 355 and 462 bookings during the reporting period.

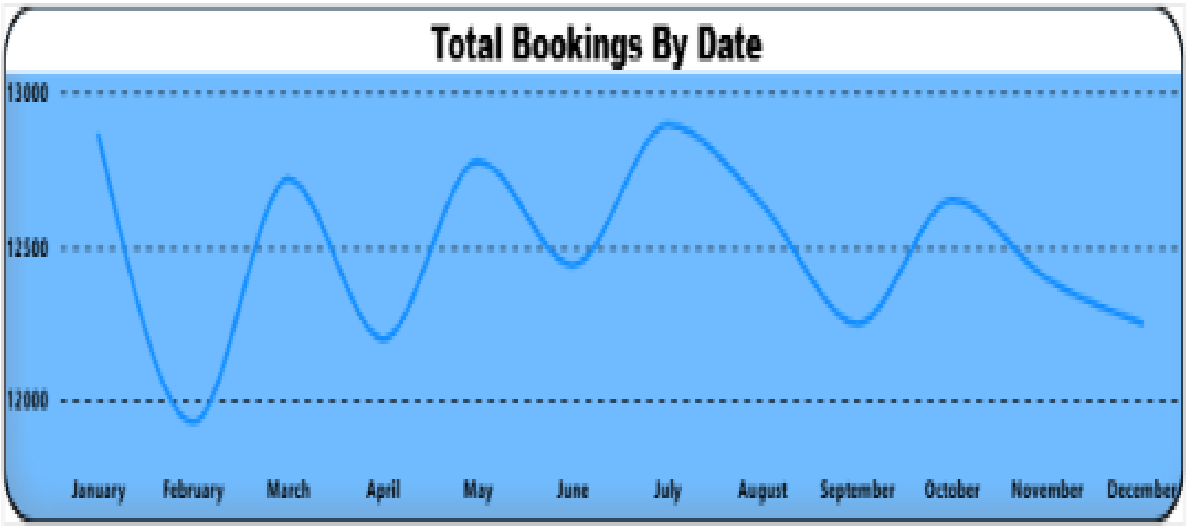

The highest daily booking volume was recorded on 16 November 2024, with 462 bookings, while 22 August 2024 recorded the lowest volume at 355.

The day-of-week analysis showed relatively consistent booking activity. Monday recorded the highest booking volume at 21,644, followed by Saturday with 21,542. Thursday recorded the lowest volume at 21,215.

The difference between the highest and lowest weekday volumes was only 429 bookings, representing approximately 2.02% of the lower figure.

Business Finding: Booking activity was relatively evenly distributed across the seven days of the week. Although individual dates showed fluctuations, the available results do not establish a substantial weekday concentration.

Figure 3: Daily Trend of Ola Ride Bookings

3.2 Booking Fulfilment and Cancellation Performance

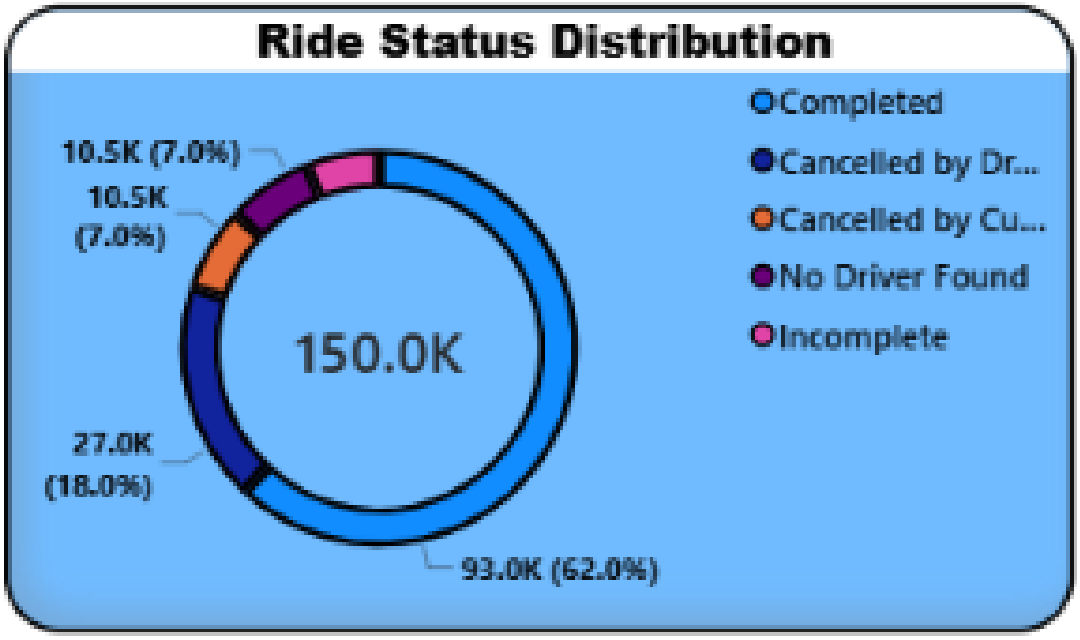

Of the 150,000 bookings analysed, 93,000 resulted in completed rides, representing an overall completion rate of 62%. The remaining 57,000 bookings, or 38%, did not result in completed rides.

Booking Outcome	Bookings	Percentage of Total
Completed	93,000	62.00%
Cancelled by Driver	27,000	18.00%
Cancelled by Customer	10,500	7.00%
No Driver Found	10,500	7.00%
Incomplete	9,000	6.00%
Total	**150,000**	**100.00%**

Driver cancellations represented 47.37% of all 57,000 unsuccessful bookings. This was the largest individual category, followed by customer cancellations and bookings where no driver was found.

Business Finding: The largest identified source of unsuccessful bookings was driver cancellation. However, bookings where no driver was found represent a separate availability issue and should be investigated independently.

Figure 4: Distribution of Ola Ride Booking Outcomes

3.3 Location-Wise Operational Performance

Pickup locations were compared using booking volume, completed rides, completion rates, unsuccessful bookings and customer ratings.

Performance Indicator	Location	Result
Highest booking volume	Khandsa	949
Highest completed rides	Khandsa	600
Highest completion rate	Welcome	66.27%
Lowest completion rate	Vinobapuri	54.68%
Highest unsuccessful booking count	Saket	374
Lowest unsuccessful booking count	Welcome	282
Highest average rating	South Extension	4.46
Lowest average rating	Yamuna Bank and IGNOU Road	4.35

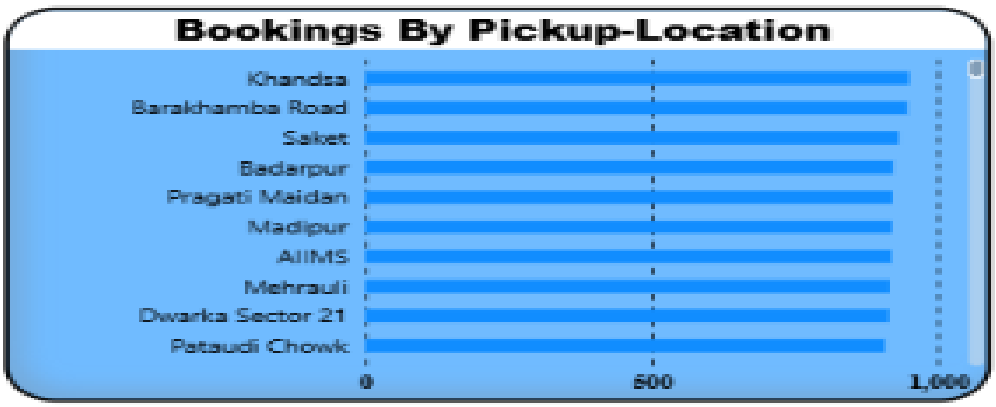

Khandsa recorded the highest booking volume and completed rides. However, Welcome achieved the highest completion rate, indicating that booking volume and fulfilment efficiency do not necessarily identify the same strongest-performing locations.

Vinobapuri recorded the lowest completion rate, 11.59 percentage points below Welcome. Saket recorded the highest number of unsuccessful bookings.

Customer ratings showed relatively limited variation across locations, ranging from 4.35 to 4.46.

Business Finding: Location-level performance differs across demand, fulfilment and customer ratings. Vinobapuri warrants investigation based on its lower completion rate, while Saket requires further examination of its unsuccessful booking volume. These comparisons should be interpreted alongside location-level booking volumes.

Figure 5: Location-Wise Ola Booking Performance

3.4 Vehicle-Wise Performance and Service Quality

Vehicle categories were compared using customer cancellations, driver cancellations, arrival times, trip times and customer ratings.

Vehicle Type	Customer Cancellations	Driver Cancellations	Total Cancellations
Auto	2,680	6,643	9,323
Bike	1,575	4,077	5,652
eBike	723	1,907	2,630
Go Mini	2,097	5,330	7,427
Go Sedan	1,832	5,031	6,863
Premier Sedan	1,266	3,250	4,516
Uber XL	327	762	1,089

Auto recorded the highest cancellation volume at 9,323, followed by Go Mini at 7,427. Uber XL recorded the lowest volume at 1,089.

These are absolute cancellation counts. They do not establish which vehicle category has the highest cancellation risk because total bookings differ across vehicle categories.

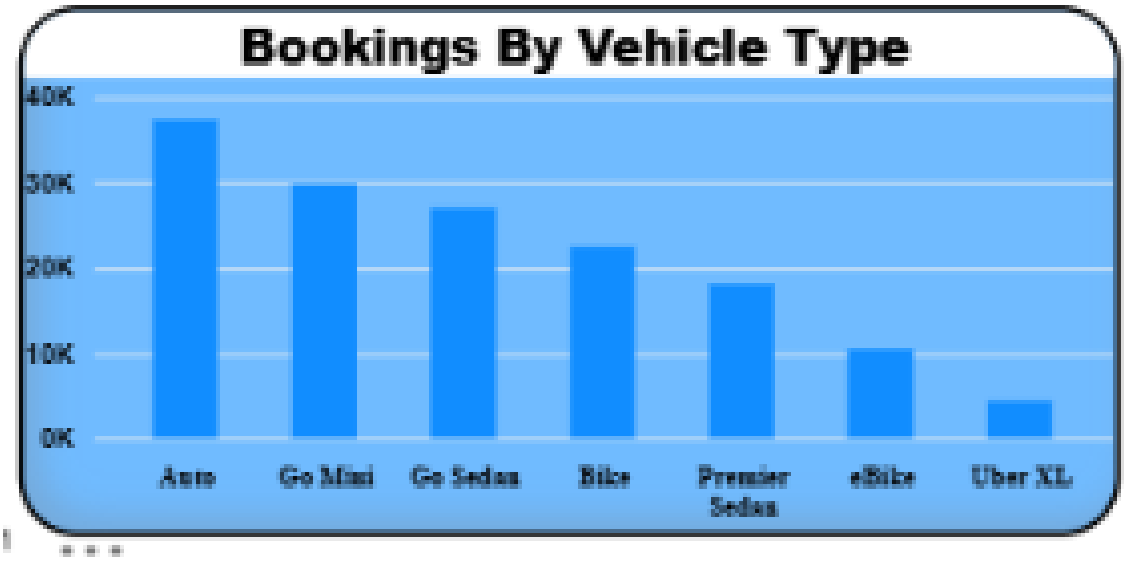

The operational analysis also showed that:

- Go Sedan recorded the lowest average VTAT at 8.40.
- Go Sedan recorded the lowest average CTAT at 29.04.
- Go Sedan achieved the highest average customer rating at 4.41.
- Uber XL recorded the highest average VTAT at 8.58.
- Premier Sedan recorded the highest average CTAT at 29.22.

Average customer ratings across the vehicle categories remained almost identical, ranging from 4.40 to 4.41.

Business Finding: Go Sedan showed comparatively favourable results across the reported waiting-time, trip-time and rating indicators. However, the differences in average ratings were marginal. Auto's higher cancellation count should be investigated using cancellation rates relative to its total bookings before identifying it as an underperforming category.

Figure 6: Booking Performance Across Vehicle Types

3.5 Cancellation Patterns and Recorded Reasons

The cancellation analysis examined recorded customer and driver cancellation reasons to identify the most frequently reported issues.

Customer cancellation reasons

Recorded Reason	Cancellations
Wrong Address	2,362
Change of Plans	2,353
Driver Not Moving Towards Pickup	2,335
Driver Asked to Cancel	2,295
AC Not Working	1,155

Wrong Address was the most frequently recorded customer cancellation reason, with 2,362 cases. However, the first four categories had relatively similar counts, indicating that customer cancellations were distributed across multiple recorded reasons.

Driver cancellation reasons

Recorded Reason	Cancellations
Customer Related Issue	6,837
Customer Coughing/Sick	6,751
Personal and Car Related Issues	6,726
More Than Permitted People	6,686

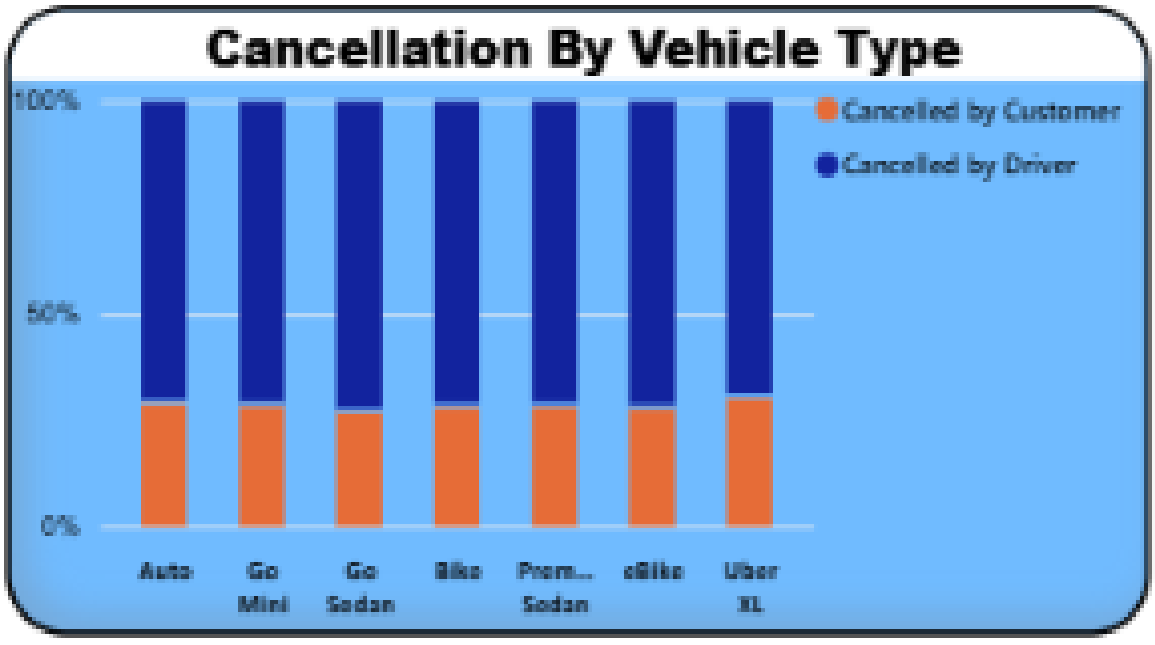

Customer Related Issue was the highest recorded driver cancellation category at 6,837 cases. The difference between the highest and lowest listed categories was only 151 cases.

Location-level analysis identified Udyog Vihar – Wrong Address as the highest individual pickup-location and cancellation-reason combination, with 28 cases.

Business Finding: Cancellation patterns are associated with multiple recorded customer and driver-related reasons. The relatively close counts across the major categories indicate that management should not concentrate exclusively on one cancellation reason.

These are recorded reasons and should not automatically be treated as verified root causes.

Figure 7: Analysis of Recorded Ride Cancellation Reasons

3.6 Payment Method and Data Completeness

Payment-method analysis showed the following distribution:

Payment Method	Total Bookings	Completed Rides
UPI	45,909	41,834
Cash	25,367	23,114
Uber Wallet	12,276	11,206
Credit Card	10,209	9,320
Debit Card	8,239	7,526
Not Available (NULL)	48,000	0

UPI recorded the highest booking volume among the available payment categories, with 45,909 bookings, followed by Cash with 25,367.

A significant data-completeness issue was identified: 48,000 records, representing 32% of the dataset, had no payment method recorded.

Of these records, 37,500 belonged to customer and driver cancellation categories, while the remaining 10,500 were unsuccessful bookings whose exact status distribution was not separately established in the reported analysis.

The absence of payment information across these records limits the completeness of payment-related reporting. Missing payment information should not be interpreted as a payment failure, particularly when a booking did not result in a completed ride.

Business Finding: UPI was the most frequently recorded payment method. However, the large volume of missing payment information restricts the ability to make complete comparisons across payment categories.

Management Implication: The company should review the point at which payment information is captured and distinguish between genuinely missing information and records where payment details are not applicable.

3.7 Booking Value and Ride-Level Analysis

Booking value was examined across ride distances and combinations of vehicle type, payment method and pickup location.

The comparison of average booking value across ride-distance groups showed fluctuations but did not establish a consistent increasing or decreasing relationship between distance and booking value.

A separate analysis identified selected vehicle-location-payment combinations with average booking values above the overall dataset average.

The highest displayed combination was Uber XL using Debit Card at Tis Hazari, with an average booking value of ₹2,222. However, this result was based on a single booking and should not be considered evidence of consistently high-value performance.

Further analysis of the top 20 vehicle-location combinations by total booking value identified:

- Auto at AIIMS recorded the highest total booking value at ₹1,02,521 across 248 bookings.
- Auto at Rohini East recorded the highest booking volume at 254.
- Auto at Rohini East also recorded the highest unsuccessful booking count at 102.
- Auto at Khandsa recorded the highest average customer rating at 4.47 among the displayed combinations.

Business Finding: Booking value, volume, ratings and unsuccessful booking counts vary across vehicle-location combinations. However, high booking value does not necessarily indicate stronger operational performance.

Comparisons should consider booking volume and unsuccessful booking rates alongside total booking value.

3.8 Time and Location-Based Unsuccessful Booking Patterns

Unsuccessful bookings were examined across vehicle types, pickup locations and hours of the day.

Auto at Saket A Block recorded the highest unsuccessful booking count among the reported vehicle-location-hour combinations, with 14 cases at 18:00.

Other combinations included:

Vehicle and Pickup Location	Hour	Unsuccessful Bookings
Auto – Saket A Block	18:00	14
Go Mini – Hauz Rani	15:00	12

Auto – Lal Quila	17:00	12
Auto – Sohna Road	17:00	12

These combinations identify specific operational segments for further investigation. However, the counts alone do not establish recurring peak-hour problems or higher cancellation risk.

A more meaningful comparison would examine unsuccessful booking rates relative to total bookings for each vehicle-location-hour combination.

Business Finding: The analysis identifies specific combinations with higher unsuccessful booking counts. These can serve as starting points for more detailed operational monitoring rather than being treated as confirmed problem areas.

3.9 Consolidated Analytical Findings

The SQL analysis highlights the following areas requiring management attention:

Area	**Key Finding**	**Business Significance**
Booking fulfilment	62% completion rate	38% of booking demand did not result in completed rides
Driver cancellations	27,000 cases	Largest individual unsuccessful booking category
Driver availability	10,500 bookings with no driver found	Separate availability concern
Location performance	Completion rates ranged from 54.68% to 66.27%	Differences in fulfilment across locations
Payment information	48,000 records without payment method	Limits payment-related analysis
Vehicle performance	Auto recorded 9,323 cancellations	Requires volume-adjusted comparison
Customer experience	Average ratings ranged from 4.35 to 4.46 across locations	Relatively narrow variation in reported ratings

These findings establish the operational areas examined further through the Power BI dashboard and management recommendations.

4. POWER BI DASHBOARD AND PERFORMANCE MONITORING

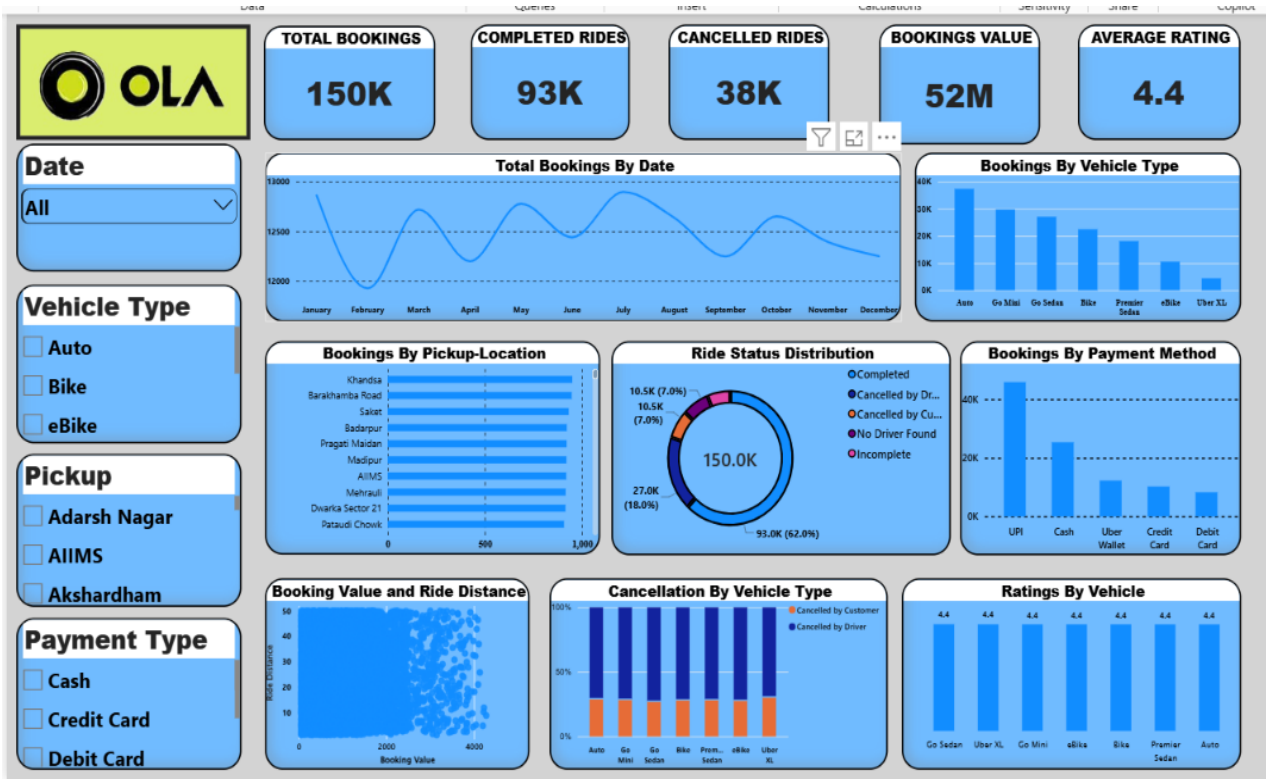

4.1 Dashboard Overview

Microsoft Power BI was used to develop an interactive dashboard consolidating the major findings from the Ola ride-booking analysis.

The dashboard presents an overview of booking activity, completed rides, cancellations, booking value and customer ratings. It allows users to examine overall performance and investigate differences across dates, vehicle types, pickup locations and payment methods.

The dashboard uses a white and blue visual theme to maintain readability and visual consistency, with KPI cards, charts and interactive slicers arranged to support operational monitoring.

Figure 8: Ola Ride Analytics Interactive Power BI Dashboard

4.2 Key Performance Indicators

Five KPI cards were included to provide an immediate overview of the company's recorded booking performance.

KPI	Reported Value
Total Bookings	150K
Completed Rides	93K
Cancelled Rides	38K
Total Booking Value	₹52M
Average Customer Rating	4.4

These indicators allow users to monitor booking volume, successful fulfilment, cancellation volume, recorded booking value and customer ratings.

Metric clarification: The 38K cancellation KPI is a rounded presentation of 37,500 customer and driver cancellations. It should not be confused with the 57,000 total unsuccessful bookings, which also include no-driver-found and incomplete outcomes.

Total booking value represents the recorded value measure in the dataset and should not automatically be interpreted as realised company revenue.

4.3 Interactive Filters

Four slicers were incorporated into the dashboard.

Slicer	Business Application
Date	Examine booking trends across selected periods
Vehicle Type	Compare operational performance by vehicle category
Pickup Location	Investigate demand and booking outcomes by location
Payment Method	Compare booking activity across recorded payment categories

These filters allow users to narrow the analysis to specific operational segments rather than relying exclusively on overall performance figures.

For example, management can select an individual vehicle category and pickup location to examine the corresponding booking volume, cancellation activity and customer ratings.

4.4 Dashboard Visualisations

Eight visualisations were developed to examine different dimensions of ride-booking operations.

Visualisation	Chart Type	Business Purpose
Total Bookings by Date	Line Chart	Monitor changes in booking demand
Bookings by Vehicle Type	Bar Chart	Compare booking volumes across vehicle categories
Bookings by Pickup Location	Stacked Bar Chart	Examine location-level booking distribution
Ride Status Distribution	Donut Chart	Understand booking outcomes
Bookings by Payment Method	Bar Chart	Compare recorded payment-method volumes
Booking Value and Ride Distance	Scatter Chart	Examine booking-value variation across ride distances
Cancellation by Vehicle Type	100% Stacked Column Chart	Compare cancellation composition across vehicle categories
Ratings by Vehicle	Bar Chart	Compare average customer ratings

Together, these visualisations provide a consolidated view of demand, fulfilment, cancellation behaviour, location activity, payment preferences and customer experience.

4.5 Business Applications of the Dashboard

The dashboard supports operational monitoring through its combination of performance indicators, visual comparisons and interactive filters.

Its principal applications include:

- Monitoring changes in daily booking activity.
- Comparing booking and cancellation volumes across vehicle categories.
- Identifying locations with different booking outcomes.
- Reviewing the distribution of completed and unsuccessful bookings.

- Examining recorded payment-method patterns.
- Comparing customer ratings across vehicle categories.
- Investigating selected booking-value and ride-distance relationships.

The dashboard is intended to support performance monitoring and identify areas requiring further analysis. It does not independently establish the underlying causes of cancellations or operational differences.

5. KEY BUSINESS INSIGHTS AND MANAGEMENT RECOMMENDATIONS

The analysis identified several areas were operational performance and data quality warrant management attention. The following recommendations prioritise the findings according to their potential relevance to booking fulfilment and operational monitoring.

5.1 Booking Fulfilment Requires Priority Attention

Finding: Only 93,000 of the 150,000 bookings resulted in completed rides, representing a completion rate of 62%. The remaining 57,000 bookings were unsuccessful.

Driver cancellations alone accounted for 27,000 cases, representing 47.37% of all unsuccessful bookings.

Business Implication: A substantial proportion of recorded booking demand did not convert into completed rides. Driver cancellations represent the largest identifiable category of unsuccessful bookings.

Recommendation: Management should prioritise investigating driver cancellation patterns, including the recorded reasons, vehicle categories, pickup locations and booking hours associated with these outcomes.

Suggested performance measure: Driver cancellation rate and overall booking completion rate.

5.2 Driver Availability and Cancellation Issues Should Be Investigated Separately

Finding: Driver cancellations accounted for 27,000 cases, while 10,500 bookings were unsuccessful because no driver was found.

Business Implication: These represent two different operational issues. Driver cancellations concern bookings that were cancelled by drivers, whereas no-driver-found outcomes indicate that a driver was not identified for the booking.

Recommendation: Review driver cancellation reasons separately from driver availability. Examine whether unsuccessful booking patterns are concentrated in particular locations, hours or vehicle categories.

Suggested performance measures: Driver cancellation rate, no-driver-found rate and booking fulfilment rate.

5.3 Location-Level Fulfilment Should Be Monitored

Finding: Welcome recorded the highest completion rate at 66.27%, while Vinobapuri recorded the lowest at 54.68%. Saket recorded the highest unsuccessful booking count at 374.

Business Implication: Location-level performance differs in terms of fulfilment and unsuccessful booking volumes. Locations with lower completion rates warrant investigation, while high-volume locations require monitoring to ensure operational capacity.

Recommendation: Investigate the factors associated with lower completion performance in Vinobapuri and examine the unsuccessful booking patterns in Saket. Compare both booking counts and completion rates before allocating operational resources.

Suggested performance measures: Location-wise completion rate, unsuccessful booking rate and completed rides.

5.4 Vehicle Performance Should Be Evaluated Using Rates

Finding: Auto recorded the highest cancellation volume at 9,323, while Uber XL recorded the lowest at 1,089. Go Sedan showed the lowest reported average VTAT and CTAT and the highest average customer rating at 4.41.

Business Implication: Cancellation counts alone do not establish vehicle-level operational efficiency because booking volumes vary across categories.

Recommendation: Calculate cancellation rates relative to total bookings for each vehicle category. Combine these comparisons with waiting times, trip times and customer ratings to identify meaningful performance differences.

Suggested performance measures: Vehicle-wise cancellation rate, completion rate, average VTAT, average CTAT and customer rating.

5.5 Cancellation Management Requires Attention to Multiple Issues

Finding: Customer cancellation reasons included Wrong Address, Change of Plans and Driver Not Moving Towards Pickup. Driver cancellation reasons included Customer Related Issue, Customer Coughing/Sick and Personal and Car Related Issues.

The leading recorded reasons had relatively similar counts within their respective categories.

Business Implication: The cancellation pattern is not concentrated in a single recorded reason. Address accuracy, booking communication, customer-related concerns and vehicle-related issues all warrant attention.

Recommendation: Improve pickup-address verification and booking communication. Review driver feedback and recorded cancellation reasons to identify issues that can be addressed through clearer operational processes.

Suggested performance measures: Cancellation rate by reason, customer cancellation rate and driver cancellation rate.

5.6 Payment Data Completeness Should Be Improved

Finding: 48,000 records, representing 32% of the dataset, did not contain a recorded payment method.

Business Implication: Missing payment information limits the reliability and completeness of payment-related reporting. It also restricts the ability to compare payment behaviour across all booking outcomes.

Recommendation: Review payment-information capture within the booking process. Establish clear distinctions between missing information, unavailable information and records where payment details are not applicable.

Suggested performance measures: Payment-method completeness rate and percentage of records with missing payment information.

5.7 Booking Value Should Be Evaluated Alongside Booking Volume

Finding: Auto at AIIMS recorded the highest total booking value among the displayed top 20 vehicle-location combinations, at ₹1,02,521 across 248 bookings. The highest average booking value in a separate combination analysis was ₹2,222, based on one booking.

Business Implication: Isolated high-value transactions do not establish consistently high-value business segments. Booking volume must be considered when comparing average booking values.

Recommendation: Prioritise comparisons that include total booking value, average booking value and booking volume. Exclude or separately identify combinations with insufficient observations when drawing management conclusions.

Suggested performance measures: Total booking value, average booking value and number of bookings.

5.8 Prioritised Management Action Plan

The findings can be translated into the following management priorities.

Priority	Management Action	Monitoring Indicator
High	Investigate driver cancellations	Driver cancellation rate
High	Examine no-driver-found bookings	No-driver-found rate
High	Investigate low-completion locations	Location-wise completion rate
Medium	Review cancellation reasons and communication issues	Cancellation rate by reason
Medium	Compare vehicle categories using booking-adjusted rates	Vehicle-wise cancellation rate
Medium	Improve payment-information recording	Payment data completeness
Medium	Monitor booking value alongside volume	Average and total booking value

The recommended actions are intended to guide further investigation and operational monitoring. Their effectiveness should be assessed using consistently defined performance measures before management concludes that an intervention has improved results.

6. CONCLUSION AND ANALYTICAL LIMITATIONS

6.1 Project Conclusion

The Ola Ride Analytics project examined 150,000 ride-booking records using Microsoft Excel, PostgreSQL and Microsoft Power BI.

The analysis identified a 62% booking completion rate, with 57,000 bookings not resulting in completed rides. Driver cancellations represented the largest individual category of unsuccessful bookings, highlighting an important area for operational investigation.

Location-level comparisons revealed differences in booking fulfilment, while vehicle-level analysis identified variations in cancellation volumes and service-quality

indicators. The analysis also highlighted missing payment-method information across 48,000 records, limiting the completeness of payment-related reporting.

By combining data preparation, SQL-based analysis and interactive Power BI reporting, the project demonstrates how operational booking data can be converted into measurable performance indicators, business insights and management recommendations.

The most important management priorities emerging from the analysis are improving booking fulfilment, investigating driver cancellation and availability patterns, monitoring location-level performance and strengthening operational data completeness.

6.2 Analytical Limitations

The findings should be interpreted within the limitations of the available dataset and analysis.

1. **Historical coverage:** The dataset covers a defined period in 2024 and may not represent current operational performance.
2. **Cancellation counts:** Absolute cancellation volumes do not establish relative cancellation risk without comparison against total bookings for each category.
3. **Recorded cancellation reasons:** The analysis uses recorded reasons and does not independently verify the underlying causes.
4. **Missing payment information:** The absence of payment-method information across 48,000 records restricts complete payment-related comparisons.
5. **Booking value interpretation:** Recorded booking value should not be treated as realised company revenue without additional financial information.
6. **Limited causal analysis:** The analysis identifies associations and operational patterns but does not establish that a particular factor directly causes cancellations or unsuccessful bookings.

Further analysis using booking-adjusted performance rates, more detailed operational data and additional time periods would help strengthen the findings and support more precise management decisions.
